Instructions: Do the following within your project team.

1. Write a set of basic SQL queries that you will need to implement your application. For this assignment, focus on those queries that only require basic select-from-where clauses, including those with joins and aggregates.

2. For each query, state where in your application the query will be required/used.

3. Implement the query in SQL (within a separate `p5.sql` script), and show that the queries are producing the correct results with respect to your populated database. Note that you may need to add additional rows to your tables to properly test your queries.

Turning in your Work. Submit your answers to the above to your project's GitHub repository.
